Project Mentor: Dr. Prabhdeep Singh ***Team ID: DSCPP-III-2026-T188***

IMPLEMENTATION AND PROGRESS

Project Summary and Phase-II Objective

The College Event Registration Platform addresses a common campus problem event details and student registrations can be spread across separate forms and spreadsheets. In Phase I we identified the problem and planned a C++ solution based on classes and data structures. In Phase II we completed the core program logic using C++ and Data structures and algorithms (DSA) website and web interface are planned for Phase III.

Work Completed Since Phase I

The Phase-II work focuses on the C++ program for managing college events and registrations the intended platform will help students browse events and register while organizers can manage event information and review registrations the website itself has not yet been built it is the main focus of Phase III.

To keep the project status accurate Phase II covers the C++ and DSA implementation only we are not claiming that a browser based website is already connected to the C++ classes. In Phase III, we will develop the website and decide how to connect the web interface with the completed project logic

Data Structures, Algorithms and Class Design

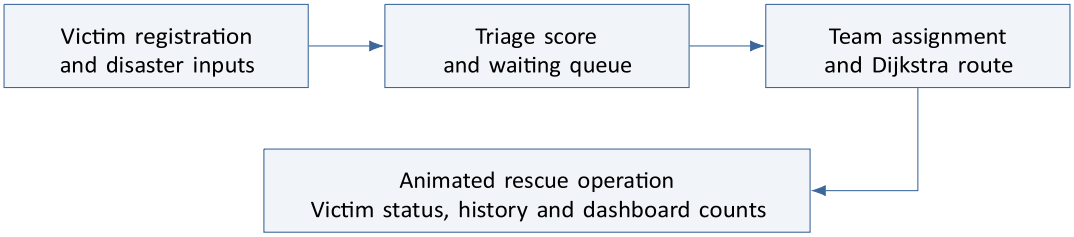

Data structures. *The C++ implementation uses the data structures actually included in our program to organize and process event, participant and registration records the final demonstration should identify each structure directly from the submitted source code and explain why it is suitable for that operation.*

Searching and record handling. *Searching can be used to locate event or registration records. Any searching or sorting algorithms discussed in the presentation should match the algorithms present in the Phase-II code no unimplemented algorithm should be described as completed.*

Registration records. *The program organizes event and registration information according to the data structures used in the C++ source In Phase III the team will design how these records are presented on the website and how they will be stored and retrieved in the integrated system.*

C++ classes. *The project uses C++ and class-based design to organize the event-registration logic Explain the exact classes, member functions encapsulation and other OOP features from the submitted source code the website integration remains future work for Phase III.*

System Architecture and Rescue Workflow

The intended workflow begins with event details being entered by an organizer, students can then view available events and submit registration information the program should validate the relevant details and update registration records according to its implemented rules. In Phase III these operations will be presented through website pages with event listings registration forms and organizer side management.

EVALUATION, CONTRIBUTIONS AND NEXT STEPS

Initial Evaluation and Test Plan

The Phase-II C++ program should be tested with repeatable cases before website integration. Mark cases as passed only after checking the current source code.

Valid event registration	**The program accepts valid registration details and stores the record correctly.**
Event capacity	Registration follows implemented rules when seats are available or event is full.
Invalid input	Invalid menu choices or incomplete detail are handled without an unintended operation.
Search record	The relevant event or registration found or a clear not-found result is shown.
Duplicate registration	Repeated registrations follow the rule which is defined in program.
Display records	Event and registration information is displayed consistently with stored records.

Individual Contributions

The team will demonstrate the work completed by each member in Phase II. The task split below should be checked and edited to match the actual contributions made by each team member.

Nikunj Singhal (ML-3): *Team coordination, C++ implementation and documentation — confirm the exact contribution before submission.*

Bhargav Istwal (ML-2): *C++ / DSA implementation and testing — confirm the exact contribution before submission.*

Harshit Kashyap (ML-4): *C++ / Scenerio Testing,dashboard and reports*

Limitations and Remaining Work

The Phase-II deliverable is the core C++ and DSA implementation the website is not yet completed the web interface, event listing pages registration forms and organizer dashboard remain for Phase III. The integration between the website and the C++ logic data storage, input validation and end-to-end testing will need to be completed and verified before the full platform can be described as finished.

Next Milestones and Phase-II Deliverables

Next up: *Review and test the completed C++ cod check registration and event management edge cases and document the results that can be reproduced In Phase III build the website interface create student and organizer pages connect the required functionality and test the complete flow from event creation through student registration.*

What we have now: *The Phase-II C++ source code and DSA-based project logic for the College Event Registration Platform the website & web integration and final end-to-end demonstration are planned for Phase III. At the next review we will distinguish the features already implemented and tested from the work that is still pending*
